Abstract

This paper introduces a new socio-inspired metaheuristic technique referred to as Ideology Algorithm (IA). It is inspired by the self-interested and competitive behaviour of political party individuals which makes them improve their ranking. IA demonstrated superior performance as compared to other well-known techniques in solving unconstrained test problems. Wilcoxon Signed-Rank Test, as a statistical tool, is applied to verify the performance of IA in solving optimization problems. The results are compared with seven well known and some recently proposed optimization algorithms (PSO, CLPSO, CMAES, ABC, JDE, SADE and BSA). A total of 75 unconstrained benchmark problems are used to test the performance of IA up to 30 dimensions. The results from this study show that IA outperforms the other algorithms in terms of number of fitness function evaluations and run time. The eminent observed features of the algorithm are also discussed.

Keywords: metaheuristic, ideology algorithm, socio-inspired optimization, unconstrained test problems

1. Introduction and Motivation

Over the last two decades, meta-heuristic optimization techniques have become increasingly popular and essential in applied mathematics [1-3]. Optimization algorithms are functioning as to find the best values for system variables under various conditions. Some well-known metaheuristics such as Particle Swarm Optimization (PSO) [4], Genetic Algorithm (GA) [5], Ant Colony Optimization (ACO) [6] are fairly well-known and they are applied in various fields of study. With regard to some drawbacks of classical optimization strategies as well as to achieve simplicity, flexibility and derivation-free mechanism, several metaheuristics have been designed [7–12].

Metaheuristics are inspired by simple concepts. They are usually related to physical phenomenon, animal's behaviour and evolutionary concepts. The simplicity allows people to simulate different natural concepts, propose new meta-heuristics, propose hybridization and improved versions. Second, the applicability of metaheuristics to a variety of problems without significant changes in the algorithms' structure makes them flexible. In other words, little problem specific information is required. Also, different techniques could be deployed to support the algorithm solving a variety of class of problems. Third, the majority of metaheuristics have derivation-free mechanisms. Metaheuristics finds the solutions stochastically in contrast with gradient-based optimization techniques. The process of optimization starts with random solution(s), and the calculation of derivative for search spaces are not needed. This makes metaheuristics appropriate to apply in real world problems. Finally, the ability of metaheuristics to avoid local optima makes them reach quickly in the close neighbourhood of the region where the global optimum could be potentially located.

Generally, metaheuristics can be classified into three main classes: evolutionary, physics-based, and swarm intelligence (SI) algorithms. Evolutionary algorithms (EA) are inspired by the concepts of evolution in nature. When the objective function for an optimization problem is non-linear and non-differentiable, EA techniques are typically used to find the global optimum [13–15]. EAs have been applied for various real world engineering problems such as reverse engineer causal networks [16], commercial computer-automated exterior lighting design [17], Nano-scale crossbar architectures [18], dynamic stochastic districting and routing problem [19], neural network classifier [20], assembly line configurations [21], configurations of mobile applications [22], electric power distribution networks [23], word sense disambiguation problem [24], surgery scheduling problems [25], image processing [26], speech recognition [27] and many other problems.

The most commonly used EA optimization techniques are based on swarm intelligence (SI) [15, 28]. SI is characterized by its unique mechanism which mimics the behaviour of swarms of social insects, flocks of birds and schools of fish. The benefits of these approaches as compared with conventional techniques are the flexibility and robustness. These properties make SI a successful design paradigm for algorithms to deal with increasingly complex problems [29]. The PSO simulates the social behaviour as a representation of the movement of organisms in the school of fish [30]. The comprehensive learning particle swarm optimizer (CLPSO) [32] and PSO2011 [33] are advanced versions of the standard PSO [4]. The ACO algorithm is proposed based on strategies of ants in accessing food sources [6]. In Artificial

Bee Colony (ABC) algorithm, the nature behaviour of honey bees in discovering food sources are mimicked [15]. The Cuckoo Search (CS) algorithm is based on the behaviour of cuckoo species by laying their eggs in other host birds' nests [31]. A recently proposed algorithm, named Covariance Matrix Adaptation Evolution Strategy (CMAES) [36], is based on basic genetic rules. The Differential Evolution (DE) algorithm [34, 35] is a population-based stochastic function minimizer. The adaptive differential evolution algorithm (JDE) [37], the parameter adaptive differential evolution algorithm (JADE) [38] and the self-adaptive differential evolution algorithm (SADE) [35] are DE's advanced versions. Another recently proposed algorithm, Backtracking Search Algorithm (BSA), is acting as a function optimizer by generating a trial individual using basic genetic operators (selection, mutation and crossover). A non-uniform crossover strategy, which is more complex than the crossover strategies used in many genetic algorithms, is used by BSA [39].

The work in this paper is motivated from ideologies which are existed in human society for ages. In the context of politics, there are numerous kind of ideologies such as conservative, socialism, left-wing, right-wing, democratic, republic, communism, etc. There are several political parties exist in the world which follow these ideologies in different forms. For example, Conservative Party and Labour Party (United Kingdom), Republican Party and Democratic Party (United States of America), Communist Party (China), and Bharatiya Janata Party (India).

This paper introduces a novel socio-inspired algorithm referred to as Ideology Algorithm (IA). The society individuals support or follow certain ideologies. These ideologies become the guide or way for the individuals to achieve their long term goals. It is motivated from the competition within the members of a political party as well as competition amongst the leaders of different parties. Every local party follows certain ideology which motivates certain individuals stay associated with that party. Once associated with a party, every individual exhibits a self-interested behaviour and competes with its party members to improve and promote its rank. Every individual looks at its own local party leader as a benchmark and tries to reach as close as possible to it. Also, the individual watches other party leaders and compares itself with that leader. This may motivate it to choose different ideology associated with another party. Furthermore, every local party leader always desires to be a global leader. In other words, it competes with the other party leaders to be a global leader. Moreover, the local party leader desires to remain at least its own party leader. Thus it also competes with the second best in the party which always desires to catch the local party leader position. In addition, the lowest rank individual following the party ideology desires to climb up in the party; however for prolonged time if it understands that following its current party ideology is not improving its rank. Such deserted individual may change the ideology and resort to another party ideology. This competitive behaviour of individuals following certain ideology to improve and climb up in the party as well as compete with other party members is modelled. The mechanism enabled the IA to solve several numerical optimization problems with superior performance in terms of solution quality and computational cost as compared with other existing algorithms.

The remainder parts in this work are organized as follows. Section 2 describes mechanism of IA. Section 3 provides the detail results of the computational experiments conducted to validate the algorithm. In Section 4, conclusions and future directions are provided.

2. Ideology Algorithm (IA)

In the context of the IA, every member or individual associated with a party is a possible solution. Its position in the party depends on the quality or fitness of its solution (objective function value). The individual with the best solution in a party is considered as local party leader and the individual best amongst all the party leaders is considered as the global leader. The local party leader competes with every other party leader with a desire to be a global leader. It also competes with the second best individual in its own party as it is challenged by the second best in the party which desires to be the local party leader. The earlier makes the party leaders explore and locate promising search space. The later forces the party leader to look for a better solution in its own local neighbourhood as well as the second best in the party. This may increase its chances of remaining as the local party leader and improve. The individual in the party with worst solution checks the difference between its own solution and the penultimate worst in the same party. If the difference is greater than a pre-specified value then such deserted individual understands that following the current party ideology is not worth for it. This makes him switchover to another party in a hope to be better off and climb up in that party. The framework makes the individual in every party to directly and indirectly compete with the same party individuals as well as other party individuals. This essentially makes every party to remain in competition and grow which motivates the individuals search for better solutions. The IA procedure is explained below in detail.

Consider a general unconstrained problem (in minimization sense) as follows:

$$\begin{aligned} &Minimize\ f(\boldsymbol{x}) = f(x_1, \dots, x_i, \dots, x_N) \\ &Subject\ to\ \Psi_i^l \le x_i \le \Psi_i^u, \qquad i = 1, \dots, N \end{aligned} \tag{1}$$

The IA procedure starts with equally dividing the entire population into P parties. In the beginning, the number of individuals M_p in every party p $(p = 1, \dots, P)$ is equal, i.e. $M_1 =, \dots, M_p, \dots, = M_P$. Also the desertion parameter T associated with the worst individual, convergence parameter ε, maximum number of iterations I_{max} and reduction factor $R \in [0,1]$ are chosen.

Step 1 *(Party Formation)*

Equally divide the sampling space associated with every variable x_i, $i = 1, \dots, N$ into P party subspaces, i.e. $\forall x_i \boldsymbol{\Psi}_i^p = \left[\Psi_i^{l,p}, \Psi_i^{u,p}\right]$, p, $p = 1, \dots, P$.

Step 2 *(Evaluation)*

From within every party $p = 1, \dots, P$ subspace $\boldsymbol{\Psi}_i^p = \left[\Psi_i^{l,p}, \Psi_i^{u,p}\right]$ associated with every variable x_i, $i = 1, \dots, N$, M_p values are randomly sampled and associated objective functions are evaluated. Then the individuals associated with every party p, $p = 1, \dots, P$ could be represented as follows:

$$\forall p \quad f\left(x_{1,m_p}, \dots, x_{i,m_p}, \dots, x_{N,m_p}\right), \qquad m_p = 1, \dots, M_p \tag{2}$$

or

$$p = \begin{bmatrix} f\left(x_{1,1}, \dots, x_{i,1}, \dots, x_{N,1}\right) \\ \vdots \\ f\left(x_{1,m_p}, \dots, x_{i,m_p}, \dots, x_{N,m_p}\right) \\ \vdots \\ f\left(x_{1,M_p}, \dots, x_{i,M_p}, \dots, x_{N,M_p}\right) \end{bmatrix}, p = 1, \dots, P$$

Step 3 *(Local Party Ranking)*

From within every party p, $p = 1, \dots, P$ the evaluated individuals are ranked from the best individual referred to as local party leader $L_{p,b}$ to the local worst individual $L_{p,w}$ as shown in Figure 2.1.

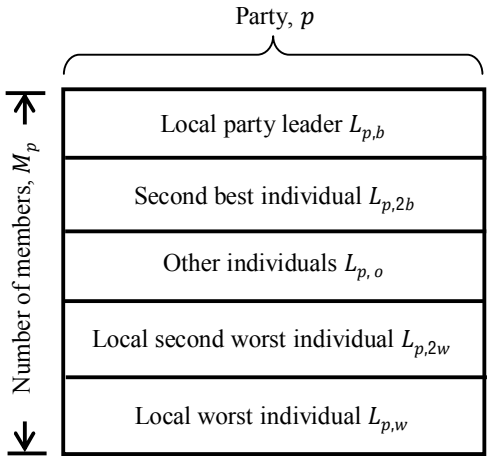

Figure 2.1: The arrangement of individuals in a party.

$$L_{p,b} = min\left(\begin{bmatrix} f(x_{1,1},\dots,x_{i,1},\dots,x_{N,1}) \\ \vdots \\ f\left(x_{1,m_p},\dots,x_{i,m_p},\dots,x_{N,m_p}\right) \\ \vdots \\ f\left(x_{1,M_p},\dots,x_{i,M_p},\dots,x_{N,M_p}\right) \end{bmatrix}\right) = f\left(x_1^{L_{p,b}},\dots,x_i^{L_{p,b}},\dots,x_N^{L_{p,b}}\right) \quad (3)$$

$$L_{p,w} = max\left(\begin{bmatrix} f(x_{1,1},\dots,x_{i,1},\dots,x_{N,1}) \\ \vdots \\ f\left(x_{1,m_p},\dots,x_{i,m_p},\dots,x_{N,m_p}\right) \\ \vdots \\ f\left(x_{1,M_p},\dots,x_{i,M_p},\dots,x_{N,M_p}\right) \end{bmatrix}\right) = f\left(x_1^{L_{p,w}},\dots,x_i^{L_{p,w}},\dots,x_N^{L_{p,w}}\right) \quad (4)$$

The second best individual $L_{p,2b}$ is worse than Local best individual $L_{p,b}$; however, better than every other individual in the party p, i.e. $L_{p,b} < L_{p,2b} < L_{p,o} < L_{p,2w} < L_{p,w}$. The Second worst individual $L_{p,2w}$ is better than the local worst individual $L_{p,w}$; however, worse than every other individual in the party p, i.e. $L_{p,w} > L_{p,2w} > L_{p,o} > L_{p,2b} > L_{p,b}$.

Step 4 *(Competition and Improvement for local party leader $L_{p,b}$)*

Every local party leader $L_{p,b}$, $(p = 1,\dots,P)$ seeks to improve itself through introspection, local competition and global competition. The *introspection* refers to searching the close neighbourhood of its own current solution by modifying the current sampling space associated with its every variable $x_i^{L_{p,b}}$, $i = 1,\dots,N$ as follows:

$$\boldsymbol{\Psi}_{i,insp}^{L_{p,b}} \in \left[x_i^{L_{p,b}} - R \times \left(\left\|\Psi_i^{u,p}\right\| - \left\|\Psi_i^{l,p}\right\|\right), x_i^{L_{p,b}} + R \times \left(\left\|\Psi_i^{u,p}\right\| - \left\|\Psi_i^{l,p}\right\|\right)\right] \quad (5)$$

The *local competition* refers to competing with the second best $L_{p,2b}$ in its own party by searching in the close neighbourhood of its current solution. In other words, the current sampling space of every variable i, $i = 1,\dots,N$ associated with every local party leader $L_{p,b}$, $(p = 1,\dots,P)$ is updated to the close neighborhood of the local best solution $L_{p,2b}$ as follows:

$$\boldsymbol{\Psi}_{i,lcmp}^{L_{p,b}} \in \left[x_i^{L_{p,2b}} - R \times \left(\left\|\Psi_i^{u,p}\right\| - \left\|\Psi_i^{l,p}\right\|\right), x_i^{L_{p,2b}} + R \times \left(\left\|\Psi_i^{u,p}\right\| - \left\|\Psi_i^{l,p}\right\|\right)\right] \quad (6)$$

Local competition is necessary as the local party leader will always try to remain the best in its own party which may further lead the algorithm to efficiently search for better solution.

The *global competition* refers to searching in the close neighbourhood of the global leader. In other words, the current sampling space of every variable $i,\ i = 1,\dots,N$ associated with every local party leader $L_{p,b}(p = 1,\dots,P)$is updated to the close neighbourhood of the global best solution $L_{p,gb}$as follows:

$$\boldsymbol{\Psi}_{i,gcomp}^{L_{p,b}} \in \left[x_i^{L_{p,gb}} - R \times \left(\left\|\Psi_i^{u,p}\right\| - \left\|\Psi_i^{l,p}\right\|\right), x_i^{L_{p,gb}} + R \times \left(\left\|\Psi_i^{u,p}\right\| - \left\|\Psi_i^{l,p}\right\|\right)\right] \tag{7}$$

where$L_{p,gb} = \min\left(L_{p,b}\right),\ p = 1,\dots,P$or $L_{p,gb} = \min\left(L_{1,b},\dots,L_{p,b},\dots,L_{P,b}\right)$

Then, the local party leader $L_{p,b}$ samples variable values from within the updated sampling intervals $\boldsymbol{\Psi}_{i,insp}^{L_{p,b}}$,$\boldsymbol{\Psi}_{i,lcmp}^{L_{p,b}}$ and $\boldsymbol{\Psi}_{i,gcomp}^{L_{p,b}}$formed using introspection, local competition and global competition, respectively and calculates corresponding objective functions. Then one solution from within the three choices is selected based on the roulette wheel selection approach [43].

For each local worst individual$L_{p,w}(p = 1,2,\dots,P)$, the distance d between itself and the second worst individual $L_{p,2w}$ is evaluated as follows:

$$d = \left\|L_{p,w} - L_{p,2w}\right\| \tag{8}$$

If the difference is higher than a pre-specified value T, then the individual understands that it is deserted (worst off) and switches over to another randomly selected party $\tilde{p} \in [1,\dots,P]$, i.e.

$$\begin{aligned} L_{p,w}^{p} &= L_{\tilde{p},w+1}^{\tilde{p}} \quad if d \geq T \\ L_{p,w}^{p} &= L_{p,o}^{p} \quad otherwise \end{aligned} \tag{9}$$

where$L_{p,o}(o = 1,2,\dots,O)$ is referred to as ordinary individual for party $(p = 1,2,\dots,P)$ and $M_p - 2 \leq O < M_p$.

Step 5*(Updating party individuals)*

Every ordinary individual $L_{p,o}(o = 1,2,\dots,O)$for every party $(p = 1,2,\dots,P)$searches one solution in its own neighbourhood $\boldsymbol{\Psi}_{i,o}^{L_{p,o}}$, every local party leader's neighborhood $\boldsymbol{\Psi}_{i,lopl}^{L_{p,o}}$, $(p = 1,2,\dots,P)$. The best O solutions are chosen from within this pool and the party individuals are updated. In other words, the current sampling space of every

variable $(i,\ i = 1, \dots, N)$ associated with every individual $L_{p,o}(o = 1, 2, \dots, O), (p = 1, \dots, P)$ other than the local party leader $L_{p,b}$ and deserted individual $L_{p,w}$ updates its sampling space in the close neighbourhood of itself (refer to Equation (10)), and every local party leader $L_{p,b}(p = 1, \dots, P)$ as w as follows:

$$\boldsymbol{\Psi}_{i,o}^{L_{p,o}} \in \left[x_i^{L_{p,o}} - R \times \left(\left\|\Psi_i^{u,p}\right\| - \left\|\Psi_i^{l,p}\right\|\right), x_i^{L_{p,o}} + R \times \left(\left\|\Psi_i^{u,p}\right\| - \left\|\Psi_i^{l,p}\right\|\right)\right] \tag{10}$$

$$\boldsymbol{\Psi}_{i,lopl}^{L_{p,o}} \in \left[x_i^{L_{p,b}} - R \times \left(\left\|\Psi_i^{u,p}\right\| - \left\|\Psi_i^{l,p}\right\|\right), x_i^{L_{p,b}} + R \times \left(\left\|\Psi_i^{u,p}\right\| - \left\|\Psi_i^{l,p}\right\|\right)\right], \quad (p = 1, \dots, P) \tag{11}$$

In this way, each individual of every party is updated.

Step 6 (*Convergence*)

The parties are considered converged if any of the following conditions satisfied, else continue to Step 1:

a) There is no significant improvement in the local party leader solutions for a significant number of iterations and/or
b) The maximum number of iterations I_{max} is reached.

It is important to mention that the number of party members may change in every iteration as some of the individuals may leave a party and join any other in hope to improve. Figure 2.2 shows the general structure of IA, where Figure 2.3 shows the flow chart of IA. The working mechanism of the IA is illustrated in Figure 2.4, where the dots represent individuals or party members and the centralized dot represents leader in a party. Figure 2.5 illustrates the movement of individuals during a run solving multimodal Ackley function. It exhibits the ability of the algorithm to quickly jump out of the local minima and reach the global minimum solution.

3. Results and Discussion

In this section, the tests and benchmark problems, statistical analysis, control parameters and convergence conditions used for the IA in the tests are presented. The performance of IA is investigated in detail. For experiments, each algorithm (PSO, CMAES, ABC, JDE, CLPSO, SADE, BSA and IA) is coded in MATLAB R2013a on Windows Platform with a T6400@4GHz Intel Core 2 Duo processor with 4GB RAM.

3.1 Benchmark Problems

Two tests are conducted to examine the performance of IA and the comparison algorithms in solving the numerical optimization problems. Test 1 involved 50 widely used benchmark problems [15, 42]. Table 3.1 summarizes several features of the benchmark problems used in Test 1. Test 2 involved 25 benchmark problems used in CEC2005 [46]. Table 3.2 summarizes several features of the benchmark problems used in Test 2.

3.2 Control Parameters

The values of the control parameters used in the experiments for IA are listed as shown in Table 3.3.

Table 3.3: The relevant control parameters used in the experiments for IA

Control Parameter	Numerical Values
Maximum number of iteration (I_{max})	30
Number of parties presented (p)	5
Initial Population size (x)	150
Random vector (R)	10000

3.3Stopping Criterion

The predetermined stopping criterion is set to terminate the algorithms.

- Stop when the absolute value of the objective function evaluations is less than10^{-16}.
- Stop when the maximum number of function evaluations reaches 200000.
- Stop when the maximum number of iterations (I_{max}) is reached.

Parametric tests have been commonly used in the analysis of experiments. For example, a common way to test whether the difference between the results of two algorithms is non-random is to apply a paired t-test, which checks whether the average difference in their performance over the problems is significantly different from zero. Non-parametric tests,

besides their original definition for dealing with nominal or ordinal data, can be also applied to continuous data by conducting ranking-based transformations, adjusting the input data to the test requirements. They can perform two classes of analysis: pairwise comparisons and multiple comparisons. Pairwise statistical procedures perform individual comparisons between two algorithms, obtaining in each application a p-value independent from another one [41]. Pairwise comparisons are the simplest kind of statistical tests that a researcher can apply within the framework of an experimental study. Such tests are directed to compare the performance of two algorithms when applied to a common set of problems. In multi-problem analysis, a value for each pair of algorithm is required (often an average value from several runs). In this section, we focus on the Sign test, which is a quick and easy procedure that can provide a clearer view about the comparison. Then, the Wilcoxon signed ranks test is introduced as an example of a simple non-parametric test for pairwise statistical comparisons.

3.4 Statistical Analysis

The Wilcoxon signed ranks test is a non-parametric procedure employed in hypothesis testing situations, involving a design with two samples. It is commonly used for answering the following question: do two samples represent two different populations? This is analogous to the paired t-test in non-parametric statistical procedures. Thus, it is a pairwise test that aims to detect significant differences between two sample means, i.e., the behaviour of two algorithms.

Table 3.4 shows the mean runtimes and simple statistical values for the results obtained in Test 1, whereas Table 3.6 lists the algorithms that obtained statistically better solutions compared with the other algorithms in Test 1, based on the Wilcoxon Signed-Rank Test. Table 3.5 shows the mean runtimes and simple statistical values for the results obtained in Test 2, whereas Table 3.7 lists the algorithms that provided statistically better solutions compared with the other algorithms in Test 2, based on the Wilcoxon Signed-Rank Test.

Table 3.8 presents the multi-problem-based pairwise statistical comparison results using the averages of the global minimum values obtained through 30 runs of IA and the comparison algorithms to solve the benchmark problems in Tests 1 and Test 2. The results indicate that IA was statistically more successful than most of the comparison algorithms with a statistical significance value $\alpha = 0.05$.

In Tables 3.6 and 3.7, a '+' sign indicates cases in which the null hypothesis is rejected and IA displays a statistically superior performance in the problem-based statistical comparison tests at the 95% significance level ($\alpha = 0.05$). The '−' sign indicates cases in which the null hypothesis was rejected and IA displayed an inferior performance; and '=' indicates cases in which there was no statistical difference between the two algorithms' success in solving the problems. The last rows of Tables 3.6 and 3.7 depict the total counts in a format of '+/=/−' for the three statistical significance cases (marked with '+', '=' or '−') in the pairwise comparison.

When the $(+/=/-)$ values are examined, it can be said that IA is statistically more successful than most of the other algorithms in solving the problems in Tests 1 and 2.

Although in Figure 3.8, the successes IA and BSA have had are statistically identical; IA has provided statistically better solutions than other algorithms.

Table 3.4: Statistical solutions obtained by PSO, CMAES, ABC, CLPSO, SADE, BSA and proposed IA in Test 1 (Mean = Mean solution; Std. Dev. = Standard-deviation of mean solution; Best = Best solution; Runtime = Mean runtime in seconds)

For pair wise comparison of the problem-solving success of EAs, a problem-based or multi-problem-based statistical comparison method can be used [41]. A problem-based comparison can use the global minimum values obtained for the problem as the result of several runs. Problem-based pair wise comparisons are widely used to determine which of two algorithms solves a specific numerical optimization problem with greater statistical success.

The global minimum values obtained are used in this paper as the result of 30 runs for its problem-based pair wise comparison of the algorithms. A multi-problem-based pairwise comparison can use the average of the global minimum values obtained as the result of several runs. Multi-problem based pairwise comparisons determine which algorithm is statistically more successful in a test that includes several benchmark problems [41].

The average of global minimum values obtained is used in this paper as the result of 30 runs for its multi problem based comparison of the algorithms. The Wilcoxon Signed-Rank Test was used for pairwise comparisons, with the statistical significance value $\alpha = 0.05$.

The null hypothesis H0 for this test is: 'There is no difference between the median of the solutions achieved by algorithm A and the median of the solutions obtained by algorithm B for same benchmark problem'. In other words, we assume that median (A) = median (B).

To determine whether algorithm A reached a statistically better solution than algorithm B, or whether the alternative hypothesis was valid, the sizes of the ranks provided by the Wilcoxon Signed-Rank Test (T+ and T- as defined in [41]) are examined thoroughly.

3.5 PSO vs IA

In PSO, the individual particles of a swarm symbolize potential solutions. They "fly" through the search space of the problem, trying to seek an optimal solution. The current positions of the particles are broadcasted to other neighbouring particles. Previously identified "good position" is then used as a starting point by the swarm for further search. On the other hand, the individual particles adjust their current positions and velocities. A distinct characteristic of PSO is its fast convergent behaviour and inherent adaptability, especially

when compared to conventional EAs [48]. Theoretical analysis of PSO [4, 30] proves that particles in a swarm can switch between an exploratory mode with large search step sizes, as well as an exploitative mode with smaller search step sizes.

Each particle in PSO is determined by its current position as shown in Equation (12), as well as its current velocity as shown in Equation (13) [49]. In each iteration, the particle's velocity is modified by its personal best position, which is the position giving the best fitness value. Also, they are determined by the global best position, which is the position of the best-fit particle from the swarm [48]. As a result, each particle searches around a region defined by its personal best position and global best position.

$$\vec{x}(t+1) = \vec{x}(t) + \vec{v}(t) + 1 \tag{12}$$

$$\vec{v}(t+1) = \omega\vec{v}(t) + \emptyset_1 rand(0,1)\left(\vec{p}(t) - \vec{x}(t)\right) + \emptyset_2 rand(0,1)\left(\vec{g}(t) - \vec{x}(t)\right) \tag{13}$$

The parameter ω is known as inertia weight and it controls the magnitude of the old velocity, $\vec{v}(t)$ to calculate the new velocity, $\vec{v}(t+1)$. The parameter $\emptyset_1$ and $\emptyset_2$ determine the significance of $\vec{p}(t)$and $\vec{g}(t)$ respectively. The procedure of PSO is as shown in Figure 3.1.

1: Initialization
2: **repeat**
3: Calculate fitness values of particles
4: Modify the best particles in the swarm
5: Choose the best particle
6: Calculate the particles' velocity
7: Update the particles' position
8: **until** convergence

Figure 3.1: General structure of PSO

The drawback of basic PSO algorithm is that it is easily suffers from the partial optimism, which leads to the less exact at its speed and the direction regulation. PSO is unable to solve the problems of scattering and optimization, as well as the problems of non-coordinate system, such as the solution to the energy field and the moving rules of the particles in the energy field [48-50]. In this paper, the proposed IA is being compared with PSO and its variants, CLPSO. The results proved that IA outperforms PSO and CLPSO in terms of run time in most of the benchmark functions of Test 1 and Test 2. The statistical

results of Test 1 as shown in Table 3.6 indicate that IA is equally good as compared with PSO and CLPSO. However, statistical results of Test 2 as shown in Table 3.7 prove that IA works better than PSO. The self-interested behaviour of every individual in IA enables them to communicate with each other in order to seek for better solutions. They respond adaptively to the shape of the fitness landscape. Thus IA is able to achieve higher convergence rate in the iterative processes. It is because the efforts of improving the best solution is not only depend on the current position of the particle itself but the position of the global best individual $(L_{p,gb})$, local best individual $(L_{p,b})$ and the local second best individual $(L_{p,2b})$. This can prevent the problem of falling into local optimum in high-dimensional space, which is the common problem faced by most of the EAs.

3.6 CMAES vs IA

The CMAES algorithm stands for Covariance Matrix Adaptation Evolution Strategy. It is a mathematical-based algorithm that makes use of adaptive mutation parameters through computing a covariance matrix as shown in Figure 3.2. [36]. One major drawback of CMAES is the cost in calculating the covariance matrix. The cost increases rapidly with increasing dimensions. Plus, sampling using a multivariate normal distribution and factorization of the covariance matrix also become increasingly expensive [49].

1: Initialization
2: **repeat**
3: Sample and validate offspring's fitness value
4: Sort the offspring by fitness
5: Perform environmental selection
6: Update the evolution path for covariance matrix adaptation
7: Update the covariance matrix
8: Update the step size
9: Update the mean
10: **until** convergence

Figure 3.2: General structure of CMAES

The IA is being compared with classical CMAES in this work. The relatively simpler structure of IA as compared with CMAES leads to the successful of IA in solving unconstrained benchmark problem in terms of run time as shown in Table 3.6 and Table 3.7. Overall the convergence speed of IA is higher than CMAES.

3.7 ABC vs IA

In ABC algorithm, the artificial bees colony is made up of employed bees, onlooker bees and scout bees. An onlooker bee waits on the dance area for making decision in choosing a food source. An employed bee goes to the previously visited food source to search for food. A scout bee carries out random search [42]. The working mechanism of ABC described in Figure 3.3.

1: Initialization
2: **repeat**
3: Place the employed bees on their food sources
4: Place the onlooker bees on the food sources depending on their nectar amounts
5: Send the scouts to the search area for discovering new food sources
6: Memorize the best food source found so far
7: **until** convergence

Figure 3.3: General structure of ABC

An existing challenge to all stochastic optimization methods is the balance between exploration and exploitation. A poor optimization will meet the problems of premature convergence and get trapped from local minima. Meanwhile, excessively exploitative will cause the algorithm to converge very slowly. ABC is good at exploration but poor at exploitation; its convergence speed is also an issue in some cases [51]. The results of the proposed IA are being compared with ABC. Results from Table 3.6 denote that IA works equally well as ABC. However, Table 3.7 shows that IA has a superior performance as compared with ABC. This proves that IA works better in dealing with high performance and more complicated benchmark functions in Test 2. Table 3.8 also prove that IA outperforms ABC as indicated in p-values as well as T- and T+ values.

3.8 DE vs IA

DE is a population-based algorithm which uses the similar operators as GA: crossover, mutation and selection. The only difference is that GA relies on crossover where DE relies on mutation operation. DE algorithm uses mutation operation as a search mechanism and selection operation to direct the search in the search space as shown in Equation (14) and Equation (15). By creating trial vectors using the components of existing individuals in the population, the crossover operator effectively sorts information about successful combinations, enabling better solution search space [15].

Mutation $$\hat{x}_i = x_{r1} + F(x_{r3} - x_{r2}), F = [0,1] \quad (14)$$

$$x_{r1}, x_{r2}, x_{r3} | r_1 \neq r_2 \neq r_3 \neq i \quad (15)$$

Crossover $$y_i^j = \begin{cases} \hat{x}_i^j, R_j \leq CR \\ x_i^j, R_j > CR \end{cases}, , R_j = [0,1] \quad (16)$$

During mutation, the parameter $\hat{x}_i$ is mutant solution vector, while F is scaling factor and i is an index of current solution. In the stage of crossover, CR is the crossover constant, while j represent the jth component of the corresponding array. In DE, a population of solution vectors is randomly created at the start. This population is successfully improved by applying mutation, crossover and selection operators as shown in Figure 3.4. In DE algorithm, each new solution produced competes with a mutant vector and the better one wins the competition. In other words, the chance of succession is independent on their fitness values. Every new solution produced competes with its parent and the better one wins the competition [15].

1: Initialization
2: Evaluation
3: **repeat**
4: Mutation
5: Recombination
6: Evaluation
7: Selection
8: **until** convergence

Figure 3.4: General structure of DE

In this section, IA is being compared with the variants modified based on of DE, which are JDE and SADE. The IA outperforms JDE and SADE in most of the benchmark functions of Test 1 and Test 2. The statistical results in Table 3.6 and Table 3.7 indicate that IA performs better than JDE and SADE.

3.9 BSA vs IA

In BSA, three basic genetic operators – selection, mutation and crossover – are used to generate trial individuals. A random mutation strategy is performed such that only one direction individual is used for each target individual. BSA randomly chooses the direction

individual from a randomly chosen individual from previous generation. BSA uses a non-uniform crossover strategy that is more complex as compared with other GAs [39]. The procedure of BSA is as shown below.

1: Initialization
2: **repeat**
3: Selection I
4: Mutation
5: Crossover
6: Selection II
7: **until** convergence

Figure 3.5: General structure of BSA

BSA is divided into five processes: initialization, selection I, mutation, crossover and selection II. In the Selection II stage, the T_is that have better fitness values than the corresponding P_is are used to update the P_is based on the concept of greedy selection. If the best individual of P (P_{best}) has better fitness value than the global minimum value, the global minimizer is updated to be P_{best}.Hence, the global minimum value is updated to be the fitness value of P_{best}.

Mutation $$Mutant = P + F(oldP - P) \tag{17}$$

Crossover $$map_{n,m} = 1, T_{n,m} := P_{n,m} \begin{cases} n \in \{1,2,3,\dots,N\} \\ m \in \{1,2,3,\dots,D\} \end{cases} \tag{18}$$

.

The proposed IA is compared with BSA. The results indicate that IA works equally well as BSA in Test 1 and Test 2 as shown in Table 3.6 and 3.7. However, Table 3.8 shows that BSA is better than IA. The unique mutation and crossover strategies of BSA make it a powerful minimization technique. However, results of Test 1 and Test 2 denote that IA has higher convergence rate as compared with BSA because of the relatively simpler structure of IA.

4. Conclusions and Future Directions

In this work, a novel socio-inspired algorithm referred to as Party Ideology Algorithm (IA), which is mainly inspired from the human society individuals following certain ideology,

is proposed. Several operators were proposed and mathematically modelled for equipping the IA with high exploration and exploitation. The performance of the proposed algorithm was benchmarked on 75 test functions in terms of exploration, exploitation, local optima avoidance, fitness improvement of the population, and convergence rate. It can be concluded that the proposed algorithm benefits from high exploitation and convergence rate.

The IA is compared to seven well-known and recent algorithms: PSO, CMAES, ABC, JDE, CLPSO, SADE, and BSA. Wilcoxon statistical tests were also conducted when comparing the algorithms. The results showed that the proposed algorithm outperforms other algorithms in the majority of test functions. The statistical tests proved that the results were statistically significant for the IA. Thus, it may be concluded from the results that the proposed IA is comparable with other algorithms. Also, it is able to be applied as alternative optimizer for different optimization problems.

It is concluded that the IA improves the overall fitness of random initial solutions on optimization problems from the overall individuals' fitness. IA effectively searches and converges towards promising search space. Thus, the proposed algorithm is able to discover different regions of an optimization problem. Other remarks that can be made from the results of this study are as follows:

- Initial random walks of individuals around the parties emphasize exploration of the search space around the individuals.
- Effective in local optima avoidance since IA employs a population of search agents to approximate the global optimum.
- Promising search spaces are ensured since individuals relocate to the position of the best individuals during optimization.
- The best individual from each iteration is saved and considered as the elite, so all individuals tend towards the best solution obtained so far as well.
- IA has very few parameters to adjust. Thus it is a flexible algorithm for solving diverse class of problems.
- The unique mechanism of IA where the local party leader competes with every other party leader and the second best individual in its own party. This motivates the party leaders to explore a greater and promising search space. Also, they continuously look for a better solution in its own local neighbourhood.
- Every individual in every party to directly and indirectly compete with the same party individuals as well as other party individuals. This makes every party to remain in competition and grow which motivates the individuals search for better solutions.

Several research directions can be recommended for future studies with the proposed algorithm. Extending this algorithm to solve multi-objective problems can be considered. In addition, the algorithm could be applied for solving real world problems from healthcare as well as supply-chain disruption domain [52].
